2019/2020

Note:

- The structure of your repository must follow the rules described in `readme.txt` and the prototypes of each function should not be changed

1. The unit tests file (`utests.zip`) should be placed and decompressed **outside** your repository folder, but in the same folder (side by side) where your repository is.

   Example:

   ```
   guest@porteus:~$ cd /media/partilha
   guest@porteus:~$ ls

   arqcp19202dag01/ utests/
   ```

2. Then, you should create an environmental variable called REPO, with the name of your repository folder.

   Example:

   ```
   guest@porteus:~$ export REPO=arqcp19202dag01
   ```

3. Now, you can compile and run the tests on the `utests` folder. The makefile on the tests will automatically include the required code from the corresponding repository folder.

   Example:

   ```
   guest@porteus:~$ cd utests/module1/ex02
   guest@porteus:~$ make run
   ```

4. As an alternative you can specify the repository when running `make`.

   Example:

   ```
   guest@porteus:~$ cd utests/module1/ex02
   guest@porteus:~$ make run REPO=arqcp19202dag01
   ```
